

SEMICONDUCTOR DEVICES HAVING A HYBRID CHANNEL LAYER,
CURRENT APERTURE TRANSISTORS AND METHODS OF FABRICATING
SAME

FIELD OF THE INVENTION

The present invention relates to semiconductor devices and, more particularly,
to current aperture transistors.

5

BACKGROUND

In high voltage/high power electronic devices, a performance characteristic of
importance may be the breakdown characteristics of the device. For example, the
maximum reverse bias blocking voltage sustainable by the device may limit the
10 potential applications for the device. In conventional transistors, the structure of the
device may result in a breakdown voltage that is less than the breakdown voltage of
the device. For example, in a conventional U-metal oxide semiconductor field effect
transistor (UMOSFET), field crowding may result at a corner of the gate trench such
that breakdown occurs in the region of the field crowding rather than in the bulk
15 material. Various structures have been proposed in different types of transistors to
provide breakdown voltages of the transistors that approach the bulk breakdown
voltage of the materials used in the transistors.

Current aperture transistors have been proposed as a potential approach to
achieve near bulk breakdown limits in nitride-based devices. **Figure 1** illustrates a
20 conventional current aperture transistor **10**. As seen in **Figure 1**, the current aperture
transistor **10** includes a silicon doped GaN drain layer **12** with spaced apart regions of
insulating GaN **14** that form the current aperture region **30**. The current aperture
region **30** is part of a regrown unintentionally doped GaN layer **16** that has an AlGaN
layer **18** formed thereon so that a two-dimensional electron gas (2DEG) forms at the
25 interface between the unintentionally doped GaN layer **16** and the AlGaN layer **18**. A
gate contact **24** and a source contact **22** are provided on the AlGaN layer **18** and a
drain contact **26** is provided on the silicon doped GaN layer **12**.

In operation, electrons from the source contact **22** flow along the 2DEG and
through the current aperture **30** to the drain contact **26**. The Schottky gate contact **24**

modulates the charge in the 2DEG to control the flow of current through the aperture. Because the pinched off region is located beneath the gate, substantial charge does not accumulate at the gate edge. Thus, the high field region may be buried in the bulk material. Further details on current aperture transistors may be found in Ben-Yaacov
5 *et al.*, "AlGaIn/GaN current aperture vertical electron transistors with regrown channels", Journal of Applied Physics, Vol. 95, No. 4, 15 February 2004, pp. 2073-78.

SUMMARY OF THE INVENTION

Some embodiments of the present invention provide transistors and/or methods of fabrication of transistors that include a source contact, drain contact and gate contact. A channel region is provided between the source and drain contacts and at least a portion of the channel regions includes a hybrid layer of semiconductor material. In particular embodiments of the present invention, the transistor is a current aperture transistor.

In further embodiments of the present invention, the hybrid layer of semiconductor material includes a Group III-nitride semiconductor material. The hybrid layer of semiconductor material may also include a region of p-type or insulating semiconductor material and a region of n-type semiconductor material. A portion of the channel region through the current aperture may include a vertical portion and a horizontal portion. The hybrid layer may include a pendeo-epitaxial layer having a higher doping level in the laterally grown portions of the pendeo-epitaxial layer. The hybrid layer may include a epitaxial laterally overgrown layer having a higher doping level in the laterally grown portions of the epitaxial laterally overgrown layer.

In additional embodiments of the present invention, the transistor includes a first n-type nitride-based layer on a substrate. The first n-type nitride-based layer has a first surface opposite the substrate and an aperture having sidewalls. A nitride-based layer is provided on the first n-type nitride-based layer and extends onto the sidewalls of the aperture. A portion of the nitride-based layer on the sidewalls of the aperture is n-type and a portion of the nitride-based layer on the first surface of the second n-type nitride-based layer is p-type and/or insulating. An unintentionally doped nitride-based layer is provided on the nitride based layer and extends to substantially fill the aperture. The unintentionally doped nitride-based layer has

portions of n-type nitride-based semiconductor material on the n-type portions of the nitride-based layer. First and second layers of nitride-based semiconductor material are provided on the unintentionally doped nitride-based layer and are configured to provide a two-dimensional electron gas (2DEG) in a region of an interface between the first and second semiconductor material layers. The source contact and the gate contact are provided on the second layer of nitride-based semiconductor material and the drain contact is electrically connected to the first n-type nitride-based layer.

In additional embodiments of the present invention, a second n-type nitride-based layer is provided between the first n-type nitride-based layer and the substrate.

In still further embodiments of the present invention, the substrate has a trench formed therein and the first n-type nitride-based layer, the nitride based layer and the unintentionally doped nitride-based layer are cantilevered over the trench.

In other embodiments of the present invention, a mask region is provided on the substrate or the second n-type nitride-based layer if present and a portion of the first n-type nitride-based layer, the nitride based layer and the unintentionally doped nitride-based layer extend onto the mask region.

Additional embodiments of the present invention include a third n-type nitride-based layer between the second nitride-based layer and the substrate. The substrate may be a silicon carbide substrate and the drain contact may be provided on the substrate opposite the first n-type nitride-based layer. An insulating layer may also be provided between the gate contact and the second layer.

In some embodiments of the present invention, the first n-type nitride-based layer includes a GaN based layer, the second n-type nitride-based layer includes a GaN based layer, the nitride-based layer on the second n-type nitride-based layer includes a GaN based layer, the unintentionally doped nitride-based layer includes a GaN based layer, the first layer includes an unintentionally doped GaN based layer and the second layer includes an AlGaN and/or InAlN based layer. The substrate may also be a GaN substrate.

In still further embodiments of the present invention, transistors and/or methods of fabricating transistors that include a substrate having a trench therein and a first pendeo-epitaxial layer of semiconductor material of the first conductivity type is provided on the substrate is provided. The first pendeo-epitaxial layer has spaced apart cantilevered portions that extend over the trench. A second pendeo-epitaxial layer of semiconductor material of a second conductivity type and/or insulating is

provided on the first pendeo-epitaxial layer of semiconductor material and includes spaced apart portions that extend from end surfaces of the cantilevered portions of the first pendeo-epitaxial layer that are the first conductivity type. A third pendeo-epitaxial layer of unintentionally doped semiconductor material is provided on the second pendeo-epitaxial layer and includes portions that extend from the spaced apart portions and coalesce and are the first conductivity type. A channel layer of semiconductor material is provided on the third pendeo-epitaxial layer and a barrier layer is provided on the channel layer. A source contact and a gate contact are provided on the barrier layer. A drain contact is electrically connected to the first layer of conformal semiconductor material.

In additional embodiments of the present invention, a first layer of conformal semiconductor material of a first conductivity type is provided on the substrate and the trench. The first pendeo-epitaxial layer may be provided on the first layer.

In further embodiments of the present invention, the first conductivity type is n-type and the second conductivity type is p-type. The semiconductor material may include a nitride-based semiconductor material. The substrate may be a GaN substrate. The substrate may also be silicon carbide. The silicon carbide substrate may be the first conductivity type and the drain contact may be provided on the silicon carbide substrate. The nitride-based semiconductor material may include a GaN based semiconductor material.

In yet further embodiments of the present invention, transistors and methods of fabricating transistors that include a mask region on a substrate are provided. A first epitaxial laterally overgrown layer of semiconductor material of the first conductivity type is provided on the substrate and at least a portion of the mask region. A second epitaxial laterally overgrown layer of semiconductor material of a second conductivity type and/or insulating is provided on the first epitaxial laterally overgrown layer of semiconductor material and at least a portion of the mask region and includes spaced apart portions that extend from end surfaces of the portions of the first epitaxial laterally overgrown layer on the mask region that are the first conductivity type. A third epitaxial laterally overgrown layer of unintentionally doped semiconductor material is provided on the second epitaxial laterally overgrown layer and includes portions that extend from the spaced apart portions and coalesce and are the first conductivity type. A channel layer of semiconductor material is provided on the third epitaxial laterally overgrown layer. A barrier layer is provided

on the channel layer. A source contact and a gate contact are provided on the barrier layer. A drain contact is electrically connected to the first layer of semiconductor material.

In further embodiments of the present invention, a first layer of semiconductor material of a first conductivity type is provided between the substrate and the first epitaxial laterally overgrown layer. The mask region may be provided on the first layer.

In additional embodiments of the present invention, the first conductivity type is n-type and the second conductivity type is p-type. The semiconductor material may be a nitride-based semiconductor material. The substrate may be silicon carbide and/or GaN. The silicon carbide substrate may be the first conductivity type and the drain contact may be provided on the silicon carbide substrate. The nitride-based semiconductor material may be a GaN based semiconductor material.

Still further embodiments of the present invention provided current aperture transistors and methods of fabricating current aperture transistors that include a first layer of semiconductor material of a second conductivity type or insulating on a substrate. A channel layer of semiconductor material is provided on the second layer. A barrier layer is provided on the channel layer. A trench extends through the barrier layer, the channel layer and the first layer. The trench includes semiconductor material of the first conductivity type therein. A gate contact and a source contact are provided on the barrier layer. The source contact is on the barrier layer and opposite the trench from the gate contact. A drain contact is electrically connected to the first layer.

In additional embodiments of the present invention, a second layer of semiconductor material of a first conductivity type is provided between the substrate and the first layer of semiconductor material. In such embodiments, the trench may extend through the first layer to and/or into the second layer.

In some embodiments of the present invention, the first conductivity type is n-type and the second conductivity type is p-type. The semiconductor material may be a nitride-based semiconductor material. The substrate may be GaN. The substrate may also be silicon carbide. The silicon carbide substrate may be the first conductivity type and the drain contact may be provided on the silicon carbide substrate opposite the first layer of semiconductor material. The nitride-based semiconductor material may be a GaN based semiconductor material. An insulating

layer may be provided between the gate contact and the barrier layer. Contact regions of semiconductor material of the first conductivity type may be provided between the source contact and the barrier layer. The trench may extend into the first layer. A third layer of semiconductor material of the first conductivity type may be disposed between the substrate and the first layer of semiconductor material.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a schematic drawing of a conventional current aperture transistor.

Figure 2 is a schematic drawing of current aperture transistors according to
5 some embodiments of the present invention.

Figures 3A-3E are schematic drawings illustrating fabrication of current aperture transistors as illustrated in **Figure 2**.

Figure 4 is a schematic drawing of current aperture transistors according to further embodiments of the present invention.

10 **Figures 5A- 5E** are schematic drawings illustrating fabrication of current aperture transistors as illustrated in **Figure 4**.

Figure 6 is a schematic drawing illustrating a current aperture transistor according to further embodiments of the present invention.

15 DETAILED DESCRIPTION OF EMBODIMENTS OF THE INVENTION

The present invention now will be described more fully hereinafter with reference to the accompanying drawings, in which embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these
20 embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. In the drawings, the size and relative sizes of layers and regions may be exaggerated for clarity. It will be understood that when an element or layer is referred to as being "on", "connected to" or "coupled to" another element or layer, it can be directly on,
25 connected or coupled to the other element or layer or intervening elements or layers may be present. In contrast, when an element is referred to as being "directly on", "directly connected to" or "directly coupled to" another element or layer, there are no intervening elements or layers present. Like numbers refer to like elements

throughout. As used herein, the term "and/or" includes any and all combinations of one or more of the associated listed items.

It will be understood that, although the terms first, second, etc. may be used herein to describe various elements, components, regions, layers and/or sections, these elements, components, regions, layers and/or sections should not be limited by these terms. These terms are only used to distinguish one element, component, region, layer or section from another region, layer or section. Thus, a first element, component, region, layer or section discussed below could be termed a second element, component, region, layer or section without departing from the teachings of the present invention.

Furthermore, relative terms, such as "lower" or "bottom" and "upper" or "top," may be used herein to describe one element's relationship to another element as illustrated in the Figures. It will be understood that relative terms are intended to encompass different orientations of the device in addition to the orientation depicted in the Figures. For example, if the device in the Figures is turned over, elements described as being on the "lower" side of other elements would then be oriented on "upper" sides of the other elements. The exemplary term "lower", can therefore, encompass both an orientation of "lower" and "upper," depending of the particular orientation of the figure. Similarly, if the device in one of the figures is turned over, elements described as "below" or "beneath" other elements would then be oriented "above" the other elements. The exemplary terms "below" or "beneath" can, therefore, encompass both an orientation of above and below.

Embodiments of the present invention are described herein with reference to cross-section illustrations that are schematic illustrations of idealized embodiments of the present invention. As such, variations from the shapes of the illustrations as a result, for example, of manufacturing techniques and/or tolerances, are to be expected. Thus, embodiments of the present invention should not be construed as limited to the particular shapes of regions illustrated herein but are to include deviations in shapes that result, for example, from manufacturing. For example, a grown or deposited region illustrated as a rectangle will, typically, have rounded or curved features and/or a gradient of concentrations at its edges with another region rather than a binary change from a first region to a second region of different composition. Thus, the regions illustrated in the figures are schematic in nature and their shapes are not

intended to illustrate the precise shape of a region of a device and are not intended to limit the scope of the present invention.

Some embodiments of the present invention provide vertical transistors that have a current aperture that is at least partially horizontal and methods of forming such transistors. In some embodiments of the present invention, the current aperture is laterally grown, for example, through lateral pendeo-epitaxial growth and/or through epitaxial lateral overgrowth (ELO). In some embodiments of the present invention, the use of lateral growth allows for the formation of a layer of semiconductor material having differing regions of conductivity types and/or differing conductivities as a result of the preferential incorporation of dopants in the laterally grown regions of the device. Such a single layer having differing lateral regions that are formed as part of a single growth or deposition process are referred to herein as a "hybrid layer." Hybrid layers may be distinguished from layers that have a substantially uniform conductivity type and/or conductivity in a lateral direction or layers that are formed of a substantially uniform conductivity type and/or conductivity that are subsequently processed by, for example, ion implantation and/or diffusion to alter the characteristics of a portion of the layer. Some embodiments of the present invention provide a transistor having at least a portion of the channel of the transistor provided by a hybrid layer.

Embodiments of the present invention may be suited for use in nitride-based vertical current aperture transistors, such as Group III-nitride based devices. As used herein, the term "Group III nitride" refers to those semiconducting compounds formed between nitrogen and the elements in Group III of the periodic table, usually aluminum (Al), gallium (Ga), and/or indium (In). The term also refers to ternary and quaternary compounds such as AlGa_N and AlInGa_N. As is well understood by those in this art, the Group III elements can combine with nitrogen to form binary (*e.g.*, GaN), ternary (*e.g.*, AlGa_N, AlIn_N), and quaternary (*e.g.*, AlInGa_N) compounds. These compounds all have empirical formulas in which one mole of nitrogen is combined with a total of one mole of the Group III elements. Accordingly, formulas such as Al_xGa_{1-x}N where $0 \leq x \leq 1$ are often used to describe them.

Figure 2 is a schematic cross sectional illustration of a current aperture transistor according to some embodiments of the present invention. As illustrated in **Figure 2**, a substrate 110, such as a silicon carbide substrate, has a trench 150 formed

therein. In some embodiments of the present invention, the trench may be from about 1 μm to about 20 μm deep and from about 0.5 μm to about 10 μm wide. As discussed below, the substrate 110 may be an n-type semiconductor material. The substrate 110 may be doped to provide a carrier concentration of from about 10^{17} to about 10^{20} cm^{-3} .

5 Alternatively, the substrate 110 may be an insulating or semi-insulating substrate. In such a case, a contact may be provided to the n+ layer 112, for example, in a trench or at a peripheral edge of the device as illustrated in **Figure 1**.

As is further illustrated in **Figure 2**, a first layer 112 of n-type semiconductor material, such as a nitride-based semiconductor material, is provided on a surface of
10 the substrate 110 and, in some embodiments, in the trench 150. The first layer 112 may, for example, be AlGaIn and may be doped with, for example, Si, Ge and/or O to provide an n+ layer of AlGaIn. In some embodiments of the present invention, the first layer 112 has a thickness of from about 0 (*i.e.* is an optional layer) to about 1 μm . The first layer 112 may also be doped to provide a carrier concentration of from about
15 10^{17} to about 10^{20} cm^{-3} . In some embodiments of the present invention where the substrate 110 is a GaN based substrate, such as a GaN substrate, the first layer 112 may be omitted.

A second layer 114 of n-type semiconductor material is provided on the first layer 112 (or the substrate if the first layer is omitted) and is cantilevered over the
20 trench 150. The second layer 114 may, for example, be an n+ GaN layer and may be formed as discussed below, by pendeo-epitaxial growth. The second layer 114 is provided on a first surface of the first layer 112 that is opposite the substrate 110 and does not extend completely across the trench 150 but includes spaced apart regions that have opposing sidewalls. In some embodiments of the present invention, the
25 second layer 114 has a thickness of from about 0.1 μm to about 5 μm . The second layer 114 also may be doped with an n-type dopant, such as Si, Ge and/or O, to provide a carrier concentration of from about 10^{17} to about 10^{20} cm^{-3} .

A third layer 116 of p-type and/or insulating semiconductor material is provided on the second layer 114 and has portions 117 of n-type semiconductor
30 material that extend from the sidewalls of the second layer 114. Thus, the third layer 116 may be provided as a hybrid layer. The third layer 116 does not extend completely across the trench 150 but includes spaced apart regions that have opposing sidewalls. In some embodiments of the present invention, the third layer 116 may be p-type or insulating GaN formed as discussed below, by pendeo-epitaxial growth in

the presence of an n-type dopant, such as Si, Ge and/or O, such that the portions 117 that are laterally grown are n-type GaN. The insulating and/or p-type regions of third layer 116 may substantially block current flow by, for example, having a Fermi level positioned at greater than about 0.5 eV from the conduction band. The portions 117
5 of the third layer 116 may be doped to provide a carrier concentration of, for example, from about 10^{14} to about 10^{19} cm⁻³. The third layer 116 may have a thickness of from about 0.1 μm to about 10 μm.

As is further illustrated in **Figure 2**, a fourth layer 118 of unintentionally doped semiconductor material is provided on the third layer 116. As discussed below,
10 the unintentionally doped semiconductor material may be lightly doped. The fourth layer 118 has portions 119 of n-type semiconductor material that extend from the sidewalls of the third layer 116. Thus, the fourth layer 118 may be provided as a hybrid layer. In some embodiments, the fourth layer 118 extends completely across the trench 150 and may coalesce where the portions 119 extending from the sidewalls
15 of the third layer 116 meet. Thus, a hole or opening 152 may be provided by the trench beneath the fourth layer 118. In some embodiments of the present invention, the fourth layer 118 may be primarily unintentionally doped GaN formed as discussed below, by pendeo-epitaxial growth in the presence of an n-type dopant, such as Si, Ge and/or O such that the portions 119 that are laterally grown are n-type GaN. The n-
20 type dopants may be affirmatively supplied and/or may be unintentional, for example, the n-type may be provided as a by-product of a prior processing step and/or contamination. The unintentionally doped regions of the fourth layer 118 may be lightly n-type or have a low net concentration of acceptors or deep levels. The portions 119 of the fourth layer 118 may be doped to provide a carrier concentration
25 of, for example, from about 10^{15} to about 10^{20} cm⁻³. The fourth layer 118 may have a thickness of from about 0.1 μm to about 10 μm.

A channel layer 120 and a barrier layer 122 may be provided on the fourth layer 118. The channel layer 120 and the barrier layer 122 are configured so as to form a 2DEG near the interface between the channel layer 120 and the barrier layer
30 122. The channel layer 120 and/or the barrier layer 122 may be provided by a single or multiple layers. In some embodiments of the present invention, the channel layer 120 is an unintentionally doped GaN layer. The barrier layer 122 may be an AlGaIn and/or AlN layer. In some embodiments of the present invention, the channel layer 120 is GaN having a thickness of from about 5 nm to about 5000 nm and the barrier

layer **122** is AlGa_N having a concentration of aluminum of from about 5 % to about 100 % and having a thickness of from about 1 nm to about 100 nm.

A gate contact **130** is provided on the barrier layer **122** and, in some embodiments, may be provided on an oxide (not shown) on the barrier layer **122**. In some embodiments of the present invention, at least a portion of the gate contact **130** overlaps with the trench **150**. In some embodiments of the present invention, the gate contact **130** is confined to a region above the trench **150**. In still further embodiments, the gate contact **130** may be provided without overlap of the trench **150**. The gate contact **130** may be formed of, for example, Ni/Au.

Optionally, a dielectric layer, such as a silicon nitride or silicon oxide layer is provided on the barrier layer **122**. In such embodiments, the gate contact **130** may be formed in a recess in the dielectric layer or, in some embodiments, may be formed on the dielectric layer.

A source contact **132** is also provided on the barrier layer **122**. Optionally, the source contact **132** may be provided on a recess into the barrier layer **122** and/or on a contact region so as to reduce resistance between the source contact **132** and the channel layer **120**. The source contact **132** may be formed of, for example, Ti/Al/Ni/Au.

A drain contact **134** is provided on the substrate **110** opposite the first layer **112**. Optionally, a backside implant or epitaxial layer (not shown) may be provided so as to reduce resistance between the drain contact **134** and the substrate **110**. The backside implant or epitaxial layer may, for example, be an n⁺ region formed in or on the substrate **110** on which the drain contact **134** is provided. Furthermore, the substrate **110** may be thinned prior to formation of the drain contact **134**. The drain contact may be formed of, for example, nickel if a silicon carbide substrate is used. As discussed above, the drain contact **134** may, optionally, be formed on the first layer **112**, similar to the configuration illustrated in **Figure 1**. In such embodiments of the present invention, an insulating substrate or a semi-insulating substrate, such as semi-insulating silicon carbide or sapphire, may be utilized for the substrate **110**.

Without wishing to be bound by any theory of operation, electrons from the source contact **132** may flow along the 2DEG formed near the interface of the barrier layer **122** and the channel layer **120** and then vertically into the n-type portions **119** of the fourth layer **118** and then laterally across the n-type portion **117** of the third layer **116** to the n⁺ layer **114**, vertically to the n⁺ layer **112** and to the drain contact **134**

through the substrate **110**. Thus, a current aperture may be provided by the p or i regions of the third layer **116** with a current path provided by the n-type regions incorporated in the laterally grown portions of the third layer **116** and the fourth layer **118**. The hole **152** may also define the current aperture. Accordingly, a portion of the channel region of the device may be provided by a hybrid layer. Furthermore, the channel region through the current aperture may include a vertical portion through the fourth layer **118** and a horizontal portion through the third layer **116**. The Schottky gate contact **130** (or MOS gate if an insulating layer provided on the barrier layer **122**) may modulate the charge in the 2DEG to control the flow of current through the aperture.

Fabrication of embodiments of the present invention as illustrated in **Figure 2** is schematically illustrated in **Figures 3A-3E**. As seen in **Figure 3A**, a substrate **110** is provided on which nitride based devices may be formed. In particular embodiments of the present invention, the substrate **110** may be an n-type silicon carbide (SiC) substrate that may be, for example, 4H polytype of silicon carbide. Other silicon carbide candidate polytypes include the 3C, 6H, and 15R polytypes. Appropriate SiC substrates are manufactured by, for example, Cree, Inc., of Durham, N.C., the assignee of the present invention, and methods for producing are described, for example, in U. S. Patent Nos. Re. 34,861; 4,946,547; 5,200,022; and 6,218,680, the contents of which are incorporated herein by reference in their entirety. Similarly, techniques for epitaxial growth of Group III nitrides have been described in, for example, U. S. Patent Nos. 5,210,051; 5,393,993; 5,523,589; and 5,292,501, the contents of which are also incorporated herein by reference in their entirety.

Optional buffer, nucleation and/or transition layers (not shown) may be provided on the substrate **110**.

Although silicon carbide may be a preferred substrate material, embodiments of the present invention may utilize any suitable substrate, such as sapphire, aluminum nitride, aluminum gallium nitride, gallium nitride, silicon, GaAs, LGO, ZnO, LAO, InP and the like. In some embodiments, an appropriate buffer layer also may be formed. In devices having an insulating or semi-insulating substrate, a second contact may be formed in a recess that extends to a drain layer opposite the current aperture from the gate.

As is further illustrated in **Figure 3A**, a trench **150** is formed in the substrate **110**, for example, by masking and etching the substrate **110**. A dry etch, wet etch or

other etch technique known to those of skill in the art may be utilized. The particular etch technique may depend on the substrate material. For example, in some embodiments of the present invention, a reactive ion etch may be utilized for a silicon carbide substrate. Other techniques for patterning the substrate to form a trench may also be utilized. For example, the trench could be provided by a saw cut or laser removal of material.

The first layer 112 is blanket formed on the substrate 110 including in the trench 150. The first layer 112 is formed conformally so as to maintain the opening 152 formed by the trench 150. The first layer 112 may be formed, for example, by plasma enhanced chemical vapor deposition (PECVD), metal organic chemical vapor deposition (MOCVD), molecular beam epitaxy (MBE), low pressure chemical vapor deposition (LPCVD) or other technique known to those of skill in the art. The particular deposition technique may depend on the composition of the first layer 112 and whether or not buffer layers such as those described above are utilized.

In some embodiments of the present invention, the first layer 112 may be omitted. For example, if the substrate 110 is a GaN substrate, the first layer 112 may be omitted and the trench may be formed in the GaN substrate.

Figure 3B illustrates formation of the second layer 114. The second layer 114 is formed by pendeo-epitaxial growth so as to be cantilevered over the opening 152 of the trench 150 and the first layer 112. Techniques for pendeo-epitaxial growth and/or epitaxial lateral overgrowth are known to those of skill in the art and need not be described further herein. However, examples of pendeo-epitaxial growth and/or epitaxial lateral overgrowth are described, for example, in United States Patent Nos. 6,582,906, 6,706,114, 6,686,261, 6,621,148, 6,608,327, 6,602,764, 6,602,763, 6,586,778, 6,582,986, 6,570,192, 6,545,300, 6,521,514, 6,489,221, 6,486,042, 6,462,355, 6,380,108, 6,376,339, 6,261,929, 6,255,198, 6,177,688 and 6,051,849, the disclosures of which are incorporated herein by reference as if set forth fully herein. The particular conditions for formation of the second layer 114 may depend on the composition of the second layer 114. Furthermore, the growth may be oriented along different facets of the crystal structure so as to provide a higher degree of impurity incorporation. Such an orientation may be provided, for example, by the orientation of the trench 150 and/or the mask 425 described below and/or the growth conditions such as temperature, ratio of source materials (*e.g.* ratio of Group III to Group V sources) and/or growth pressure.

The second layer **114** may be grown in the presence of an n-type dopant, for example, for a GaN second layer **114**, Si, Ge and/or O may be incorporated in the second layer **114** so as to provide an n+ second layer **114**. During lateral growth of the second layer **114**, the laterally grown portion may be more susceptible to
5 incorporation of the dopant and, therefore, the laterally grown portions (illustrated by the dotted line in **Figure 2**) may have a higher dopant concentration than the vertically grown portions of the second layer **114**. Thus, while the second layer **114** is illustrated as an n+ layer, the dopant concentration and, accordingly, the carrier concentration, may differ in different regions of the second layer **114**.

Figure 3C illustrates the formation of the third layer **116**. The third layer **116** is also cantilevered over the opening **152** of the trench **150**. The third layer **116** may be formed by pendeo-epitaxial growth as described above. The third layer **116** is formed as insulating or p-type semiconductor material and may be formed in the presence of a small amount of n-type dopant, such as Si, by for example, including
15 SiH₄ in the reaction chamber when the third layer **116** is grown. For a GaN based layer, a p-type dopant, such as Mg, Zn or Be, may may be provided during formation of the third layer **116**. An insulating GaN layer may be formed in the absence of a dopant other than that discussed herein with regard to the n-type laterally grown region of the third layer **116** and/or in the presence of a compensating dopant, such as
20 Fe. The quantity of n-type dopant provided may depend on the composition of the third layer **116**. However, the quantity should be sufficiently small so that the vertically grown portions of the third layer **116** are provided as p-type or insulating despite the presence of the n-type dopant (e.g. the p-type dopant or compensating dopant swamps the n-type dopant absent the preferential incorporation of n-type
25 dopant provided by lateral growth) but sufficiently large so that the preferential incorporation of the n-type dopant in the laterally grown portions of the third layer **116** provide n-type regions.

Figure 3D illustrates formation of the fourth layer **118**. The fourth layer is formed by pendeo-epitaxial growth as discussed above and may be grown to cover the
30 opening **152** of the trench **150**. Portions of the fourth layer **118** may be laterally grown to coalesce over the trench **150**. The fourth layer **118** is formed as an unintentionally doped layer and may be formed in the presence of a small amount of n-type dopant, such as Si, by for example, including SiH₄ in the reaction chamber when the fourth layer **118** is grown. The quantity of n-type dopant provided may

depend on the composition of the fourth layer 118. However, the quantity should be sufficiently small so that the vertically grown portions of the fourth layer 118 incorporate only an insubstantial amount of the n-type dopant and, thus, may be considered unintentionally doped. The quantity of n-type dopant should, however, be sufficiently large so that the preferential incorporation of the n-type dopant in the laterally grown portions of the fourth layer 118 provides n-type regions.

Figure 3E illustrates formation of the channel layer 120 and the barrier layer 122. Such layers may be formed by conventional fabrication techniques based on the composition of the respective layers. A drain contact 134, a source contact 132 and a gate contact 130 may be formed on the barrier layer utilizing conventional techniques as illustrated in Figure 2. In some embodiments of the present invention, the gate contact may be formed on a dielectric layer (not shown) on the barrier layer 122.

Figure 4 illustrates a transistor according to further embodiments of the present invention. As seen in Figure 4, a first layer 412 of n-type semiconductor material is provided on a substrate 410, such as an n-type semiconductor material substrate. The substrate 410 may be a silicon carbide substrate as described above with reference to the substrate 110. The substrate 410 may be doped to provide a carrier concentration of from about 10^{17} to about 10^{20} cm^{-3} . Alternatively, the substrate 410 may be an insulating or semi-insulating substrate. In such a case, a contact may be provided to the n+ layer 414, for example, in a trench or at a peripheral edge of the device as illustrated in Figure 1.

As is further illustrated in Figure 4, a first layer 412 of n-type semiconductor material, such as a nitride-based semiconductor material, is provided on a surface of the substrate 410. The first layer 412 may, for example, may be AlGaN and may be doped with, for example, Si to provide an n-type layer of AlGaN. In some embodiments of the present invention, the first layer 412 has a thickness of from about 0 (*i.e.* is optional) to about 1 μm . The first layer 412 may also be doped to provide a carrier concentration of from about 10^{17} to about 10^{20} cm^{-3} .

A second layer 414 of n-type semiconductor material is provided on the first layer 412. The second layer 414 may, for example, be an n+ GaN layer. The second layer 414 is provided on a first surface of the first layer 412 that is opposite the substrate 410. In some embodiments of the present invention, the second layer 414 has a thickness of from about 0.1 μm to about 10 μm . The second layer 414 also may be doped to provide a carrier concentration of from about 10^{17} to about 10^{20} cm^{-3} .

Mask regions **425** are formed on the second layer **414**. The mask regions correspond to a region of the current aperture and, in some embodiments, may be provided sufficiently thin such that during the growth of the subsequent layers, the center is etched away leaving an interior opening. The mask regions **425** may suppress vertical growth from the second layer **414**. The mask regions **425** may be, for example, an oxide such as silicon dioxide.

In some embodiments of the present invention, the first layer **412** and/or second layer **414** may be omitted. For example, if the substrate **410** is a GaN substrate, the first layer **412** and/or the second layer **414** may be omitted and the mask **425** may be provided on the substrate **410**.

A third layer **416** of n+ semiconductor material is provided on the second layer **414** and laterally overgrows at least a portion of the mask regions **425**. The third layer **416** does not completely cover the mask regions **425** and has spaced apart sidewalls. In some embodiments of the present invention, the third layer **416** may be n-type GaN formed as discussed above using epitaxial lateral overgrowth. The third layer **416** may be doped to provide a carrier concentration of, for example, from about 10^{17} to about 10^{20} cm^{-3} . The third layer **416** may have a thickness of from about 0.1 μm to about 10 μm .

A fourth layer **418** of p-type or insulating semiconductor material is provided on the third layer **416** and at least a portion of the mask regions **425** and has portions **419** of n-type semiconductor material that extend from the sidewalls of the third layer **416**. Thus, the fourth layer **418** may be provided as a hybrid layer. The fourth layer **418** does not extend completely across the mask regions **425** but includes spaced apart regions that have opposing sidewalls. In some embodiments of the present invention, the fourth layer **418** may be p-type or insulating GaN formed as discussed above, by epitaxial lateral overgrowth in the presence of an n-type dopant, such as Si, Ge or O, such that the portions **419** that are laterally grown are n-type GaN. The insulating and/or p-type regions of fourth layer **418** may substantially block current flow by, for example, having a Fermi level positioned at greater than about 0.5 eV from the conduction band. The portions **419** of the fourth layer **418** may be doped to provide a carrier concentration of, for example, from about 10^{14} to about 10^{19} cm^{-3} . The fourth layer **418** may have a thickness of from about 0.1 μm to about 10 μm .

As is further illustrated in **Figure 4**, a fifth layer **420** of unintentionally doped semiconductor material is provided on the fourth layer **418**. The fifth layer **420** has

portions 421 of n-type semiconductor material that extend from the sidewalls of the fourth layer 418. Thus, the fifth layer 420 may be provided as a hybrid layer. In some embodiments, the fifth layer 420 extends completely between the sidewalls of the fourth layer 418 and may coalesce where portions extending from the sidewalls of the fourth layer 418 meet. In some embodiments of the present invention, the fifth layer 420 may be primarily unintentionally doped GaN formed as discussed elsewhere herein, by epitaxial lateral overgrowth in the presence of an n-type dopant, such as Si such that the portions 421 that are laterally grown are n-type GaN. The unintentionally doped regions of the fifth layer 420 may be lightly n-type or have a low net concentration of acceptors or deep levels. The portions 421 of the fifth layer 420 may be doped to provide a carrier concentration of, for example, from about 10^{15} to about 10^{20} cm^{-3} . The fifth layer 420 may have a thickness of from about 0.1 μm to about 10 μm .

A channel layer 422 and a barrier layer 424 may be provided on the fifth layer 420. The channel layer 422 and the barrier layer 424 are configured so as to form a 2DEG near the interface between the channel layer 422 and the barrier layer 424. The channel layer 422 and/or the barrier layer 424 may be provided by a single or multiple layers. In some embodiments of the present invention, the channel layer 422 is an unintentionally doped GaN layer. The barrier layer 424 may be an AlGaN and/or AlN layer. In some embodiments of the present invention, the channel layer 422 is GaN having a thickness of from about 5 nm to about 5000 nm and the barrier layer 424 is AlGaN having a concentration of aluminum of from about 5% to about 100% and having a thickness of from about 1 to about 10 nm.

A gate contact 130 is provided on the barrier layer 424 and, in some embodiments, may be provided on an oxide (not shown) on the barrier layer 424. In some embodiments of the present invention, at least a portion of the gate contact 130 overlaps with the region above the mask regions 425. In some embodiments of the present invention, the gate contact 130 is confined to a region above the mask 425 and circumscribed by the mask 425. In still further embodiments, the gate contact 130 may be provided without overlap of the mask 425. The gate contact 130 may be formed of, for example, Ni/Au.

Optionally, a dielectric layer, such as a silicon nitride or silicon oxide layer is provided on the barrier layer 424. In such embodiments, the gate contact 130 may be

formed in a recess in the dielectric layer or, in some embodiments, may be formed on the dielectric layer.

A source contact **132** is also provided on the barrier layer **424**. Optionally, the source contact **132** may be provided on a recess in to the barrier layer **424** and/or on a contact region so as to reduce resistance between the source contact **132** and the channel layer **120**. The source contact **132** may be formed of, for example, Ti/Al/Ni/Au.

A drain contact **134** is provided on the substrate **410** opposite the first layer **412**. Optionally, a backside implant or epitaxial layer (not shown) may be provided so as to reduce resistance between the drain contact **134** and the substrate **410**. The backside implant or epitaxial layer may, for example, be an n⁺ region formed in or on the substrate **410** on which the drain contact **134** is provided. Furthermore, the substrate **410** may be thinned prior to formation of the drain contact **134**. The drain contact may be formed of, for example, nickel, if a silicon carbide substrate is used. As discussed above, the drain contact **134** may, optionally, be formed on the first layer **412**, similar to the configuration illustrated in **Figure 1**. In such embodiments of the present invention, an insulating substrate or a semi-insulating substrate, such as semi-insulating silicon carbide or sapphire, may be utilized for the substrate **410**.

Without wishing to be bound by any theory of operation, electrons from the source contact **432** may flow along the 2DEG formed near the interface of the barrier layer **424** and the channel layer **422** and then vertically into the n-type portions **421** of the fifth layer **420** and then laterally across the n-type portion **419** of the fourth layer **418** to the n⁺ layer **416**, vertically to the n⁺ layer **414** and the first layer **412** and to the drain contact **134** through the substrate **410**. Thus, a current aperture may be provided by the p or i regions of the fourth layer **418** with a current path provided by the n-type regions incorporated in the laterally grown portions of the fourth layer **418** and the fifth layer **410**. The current aperture may also be defined by the mask **425**.

Accordingly, a portion of the channel region of the device may be provided by a hybrid layer. Furthermore, the channel region through the current aperture may include a vertical portion through the fifth layer **420** and a horizontal portion through the fourth layer **418**. Current may also flow through the opening in the mask **425** if such opening is provided. The Schottky gate contact **130** (or MOS gate if an insulating layer provided on the barrier layer **424**) may modulate the charge in the 2DEG to control the flow of current through the aperture.

Fabrication of embodiments of the present invention as illustrated in **Figure 4** is schematically illustrated in **Figures 5A-5E**. As seen in **Figure 5A**, a substrate **410** is provided on which nitride based devices may be formed. Fabrication of the substrate **410** may be provided as discussed above with reference to the substrate **110**.

5 The first layer **412** and the second layer **414** are sequentially formed on the substrate **410**. The first layer **412** and/or second layer **414** may be formed, for example, by plasma enhanced chemical vapor deposition (PECVD), metal organic chemical vapor deposition (MOCVD), molecular beam epitaxy (MBE), low pressure chemical vapor deposition (LPCVD) or other technique known to those of skill in the art. The particular deposition technique may depend on the composition of the first layer **412** and/or the second layer **414**.

10 **Figure 5A** further illustrates formation of the mask region **425**. The mask region **425** may, for example, be fabricated by depositing an oxide layer onto the second layer **414** and then selectively etching the deposited oxide layer, for example, using a subsequent etch mask, to provide the mask region **425**. Alternatively or additionally, a mask could be formed on the second layer **414** and the oxide layer selectively deposited in openings in the mask. Variable thickness of the mask regions **425** may result from etching of the mask during subsequent growth operations as a result of the high growth temperatures. In some embodiments of the present invention, the mask has a thickness such that an opening at the interior of the mask results from this etching. In other embodiments of the present invention, the thickness is such that a portion of the mask remains and no opening is formed.

20 **Figure 5B** illustrates formation of the third layer **416**. The third layer **416** is formed by epitaxial lateral overgrowth so as to extend partly over the mask region **425** and on the second layer **414**. Techniques for epitaxial lateral overgrowth are known to those of skill in the art and are described above. The particular conditions for formation of the third layer **416** may depend on the composition of the third layer **416**. As is further seen in **Figure 5B**, the mask region **425** may be partially etched by the high temperature growth of the third layer **416**. Thus, the mask region **425** may have a tapered structure as the portions of the mask region **425** where no growth has occurred will be exposed and, therefore, etched for a longer period of time. Accordingly, in some embodiments of the present invention, the growth of the third layer **416** is carried out at a temperature sufficient to etch the mask region **425**.

The third layer **416** may be grown in the presence of an n-type dopant, for example, for a GaN third layer **416**, Si, Ge or O may be incorporated in the third layer **416** so as to provide an n⁺ third layer **416**. During lateral growth of the third layer **416**, the laterally grown portion may be more susceptible to incorporation of dopant and, therefore, the laterally grown portions (illustrated by the dotted line in **Figure 4**) may have a higher dopant concentration than the vertically grown portions of the third layer **416**. Thus, while the third layer **416** is illustrated as an n⁺ layer, the dopant and accordingly the carrier concentration, may differ in different regions of the second layer **416**.

Figure 5C illustrates the formation of the fourth layer **418**. The fourth layer **418** also extends over a portion of the mask region **425**. The fourth layer **418** may be formed by epitaxial lateral overgrowth as described above. The fourth layer **418** is formed as insulating or p-type semiconductor material and may be formed in the presence of a small amount of n-type dopant, such as Si, by for example, including SiH₄ in the reaction chamber when the fourth layer **418** is grown. For a GaN based layer, a p-type dopant, such as Mg, Zn or Be, may be provided during formation of the fourth layer **418**. An insulating GaN layer may be formed in the absence of a dopant other than that discussed herein with regard to the n-type laterally grown region of the fourth layer **418** and/or in the presence of a compensating dopant, such as Fe. The quantity of n-type dopant provided may depend on the composition of the fourth layer **418**. However, the quantity should be sufficiently small so that the vertically grown portions of the fourth layer **418** are provided as p-type or insulating despite the presence of the n-type dopant (*e.g.* the p-type dopant or compensating dopant swamps the n-type dopant absent the preferential incorporation of n-type dopant provided by lateral growth) but sufficiently large so that the preferential incorporation of the n-type dopant in the laterally grown portions **419** of the fourth layer **418** results in n-type regions.

As is further seen in **Figure 5C**, the mask region **425** may be further etched by the high temperature growth of the fourth layer **418**. Thus, the mask region **425** may have a tapered structure as the portions of the mask region **425** where no growth has occurred will be exposed and, therefore, etched for a longer period of time. Accordingly, in some embodiments of the present invention, the growth of the fourth layer **418** is carried out at a temperature sufficient to etch the mask region **425**.

Figure 5D illustrates formation of the fifth layer **420**. The fifth layer **420** is formed by epitaxial lateral overgrowth as discussed above and may be grown to cover the mask region **425** and the region between the mask regions **425**. Portions of the fifth layer **420** may be laterally grown to coalesce. The fifth layer **420** is formed as an unintentionally doped layer and may be formed in the presence of a small amount of n-type dopant, such as Si, by for example, including SiH_4 in the reaction chamber when the fifth layer **420** is grown. The quantity of n-type dopant provided may depend on the composition of the fifth layer **420**. However, the quantity should be sufficiently small so that the vertically grown portions of the fifth layer **420** incorporate only an insubstantial amount of the n-type dopant and, thus, may be considered unintentionally doped. The quantity of n-type dopant should, however, be sufficiently large so that the preferential incorporation of the n-type dopant in the laterally grown portions **421** of the fifth layer **420** results in n-type regions.

As is further seen in **Figure 5D**, the mask region **425** may be partially etched by the high temperature growth of the fifth layer **420**. In some embodiments, the mask region **425** may be completely etched through in an interior portion. Thus, the mask region **425** may have a tapered structure as the portions of the mask region **425** where no growth has occurred will be exposed and, therefore, etched for a longer period of time. Accordingly, in some embodiments of the present invention, the growth of the fifth layer **420** is carried out at a temperature sufficient to etch the mask region **425**.

Figure 5E illustrates formation of the channel layer **422** and the barrier layer **424**. Such layers may be formed by conventional fabrication techniques based on the composition of the respective layers. A drain contact **134**, a source contact **132** and a gate contact **130** may be formed utilizing conventional techniques as illustrated in **Figure 4**. In some embodiments of the present invention, the gate contact may be formed on a dielectric layer (not shown) on the barrier layer **424**.

Depending on the particular composition of the layers/regions and/or contacts illustrated in **Figures 2, 3A-3E, 4** and/or **5A-5E**, an anneal or multiple anneals may be carried out to activate dopants and/or anneal contacts. Such annealing techniques are known to those of skill in the art and, therefore, need not be described further herein.

Figure 6 illustrates a transistor according to further embodiments of the present invention. In **Figure 6**, the layer structure of the transistor may be formed and

a trench subsequently formed through the layer structure and filled with n-type semiconductor material to provide the current aperture. As seen in **Figure 6**, a first layer **612** of n-type semiconductor material is provided on a substrate **610**, such as an n-type semiconductor material substrate. The substrate **610** may be a silicon carbide substrate as described above with reference to the substrate **110**. The substrate **610** may be doped to provide a carrier concentration of from about 10^{17} to about 10^{20} cm^{-3} . Alternatively, the substrate **610** may be an insulating or semi-insulating substrate. In such a case, a contact may be provided to the n+ layer **614**, for example, in a trench or at a peripheral edge of the device as illustrated in **Figure 1**. In such embodiments, the first layer **612** may be omitted or provided as a buffer layer.

As is further illustrated in **Figure 6**, a first layer **612** of n-type semiconductor material, such as a nitride-based semiconductor material, is provided on a surface of the substrate **610**. The first layer **612** may, for example, may be AlGaN and may be doped with, for example, Si to provide an n-type layer of AlGaN. In some embodiments of the present invention, the first layer **612** has a thickness of from about 0 (*i.e.* the first layer is optional) to about 1 μm . The first layer **612** may also be doped to provide a carrier concentration of from about 10^{17} to about 10^{20} cm^{-3} .

A second layer **614** of n-type semiconductor material is provided on the first layer **612**. The second layer **614** may, for example, be an n+ GaN layer. The second layer **614** is provided on a first surface of the first layer **612** that is opposite the substrate **610**. In some embodiments of the present invention, the second layer **614** has a thickness of from about 0.1 μm to about 10 μm . The second layer **614** also may be doped to provide a carrier concentration of from about 10^{17} to about 10^{20} cm^{-3} .

A third layer **616** of p-type or insulating semiconductor material is provided on the second layer **614**. In some embodiments of the present invention, the third layer **616** may be p-type or insulating GaN formed as discussed above. The insulating and/or p-type regions of third layer **616** may substantially block current flow by, for example, having a Fermi level positioned at greater than about 0.5 eV from the conduction band. The third layer **616** may have a thickness of from about 0.1 μm to about 10 μm .

A channel layer **618** and a barrier layer **620** may be provided on the third layer **616**. The channel layer **618** and the barrier layer **620** are configured so as to form a 2DEG near the interface between the channel layer **618** and the barrier layer **620**. The channel layer **618** and/or the barrier layer **620** may be provided by a single or multiple

layers. In some embodiments of the present invention, the channel layer **618** is an unintentionally doped GaN layer. The barrier layer **620** may be an AlGaN and/or AlN layer. In some embodiments of the present invention, the channel layer **618** is GaN having a thickness of from about 5 nm to about 5 μ m and the barrier layer **620** is AlGaN having a concentration of aluminum of from about 5% to about 100% and having a thickness of from about 1 nm to about 100 nm.

Optionally, a dielectric layer **626**, such as a silicon nitride or silicon oxide layer is provided on the barrier layer **620**. A trench **622** is formed through the dielectric layer **626**, the barrier layer **620**, the channel layer **618** and the third layer **616** and extends to, and in some embodiments, into the second layer **614**. A region of n-type semiconductor material **624**, such as a nitride-based semiconductor material, such as GaN, is provided in the trench **622**.

In some embodiments of the present invention, the first layer **612** and/or second layer **614** may be omitted. For example, if the substrate **610** is a GaN substrate, the first layer **612** and/or the second layer **614** may be omitted and the trench **622** may be provided to extend to and/or into the substrate **610**.

A gate contact **630** is provided on the dielectric layer **626** and, in some embodiments, may be provided directly on the barrier layer **620**. The gate contact may be adjacent and spaced apart from the trench **622**. The gate contact **630** may be formed of, for example, Ni/Au.

Source contact regions **628** may be provided of n-type semiconductor material, such as a nitride-based semiconductor material including, for example, GaN. The source contact regions **628** extend through the dielectric layer **626** to the barrier layer **620**. A source contact **632** is also provided on the barrier layer **620**. Optionally, the source contact **632** may be provided on a recess in the barrier layer **620**. The source contact **632** may be formed of, for example, Ti/Al/Ni/Au.

A drain contact **634** is provided on the substrate **610** opposite the first layer **612**. Optionally, a backside implant (not shown) may be provided so as to reduce resistance between the drain contact **634** and the substrate **610**. The backside implant may, for example, be an n⁺ region formed in the substrate **610** on which the drain contact **634** is provided. Furthermore, the substrate **610** may be thinned prior to formation of the drain contact **634**. The drain contact may be formed of, for example, nickel, for a silicon carbide substrate. As discussed above, the drain contact **634** may, optionally, be formed on the first layer **612** or the second layer **614**, similar to the

configuration illustrated in **Figure 1**. In such embodiments of the present invention, an insulating substrate or a semi-insulating substrate, such as semi-insulating silicon carbide or sapphire, may be utilized for the substrate **610**.

5 Without wishing to be bound by any theory of operation, electrons from the source contact **632** may flow from the n-type contact regions **628** along the 2DEG formed near the interface of the barrier layer **620** and the channel layer **618** and then into the n-type region **624** to the n+ layer **614** and the first layer **612** and to the drain contact **634** through the substrate **610**. The gate contact **630** (or Schottky gate if an insulating layer is not provided on the barrier layer **620**) may modulate the charge in
10 the 2DEG to control the flow of current through the aperture.

In the drawings and specification, there have been disclosed typical embodiments of the invention, and, although specific terms have been employed, they have been used in a generic and descriptive sense only and not for purposes of limitation, the scope of the invention being set forth in the following claims.
